CRC for Australian Weed Management

The introduced flora of Australia and its weed status

By R.P. Randall | CRC for Australian Weed Management
Department of Agriculture and Food, Western Australia

CRC Weed management

Acknowledgments

A great deal of time and effort has gone into this publication. Nevertheless, as there is no definitive listing of Australian native species there may be some native plants listed in this book as introduced exotics. It is also very likely that many more exotic plants are present in Australia then have been listed here.

I take full responsibilty for any errors or omissions and would appreciate it if users of this book would please contact me with any corrections or additions via my email address: rprandall@agric.wa.gov.au

I would like to thank the Weeds CRC for supporting this project, especially the project members, and in particular my friend Dane Panetta for his ongoing support.

Furthermore many, many thanks to all those people who helped with this project including the provision of personal data, unpublished papers and various comments, aid and assistance of many forms during the last six years. They are, in no particular order, and certainly not restricted to:

Barbara Waterhouse *
Rachel McFadyen
Andrew Mitchell *
Dane Panetta
John Hosking *
Sandy Lloyd
Paul Pheloung *
Greg Keighery
Peter Williams *
David Cooke
Kate Blood
Cindy Hanson
Louise Hucks
John Virtue

Foreword

Invasive plants are species that have entered Australia from elsewhere, and which are now causing economic, social or environmental harm. In the 200 years since the arrival of Europeans, over 28,000 foreign plants have been brought to Australia, most deliberately imported for pasture, horticulture or as ornamentals. Their impact is enormous – invasive plants are the main threat to 45% of threatened and endangered species and ecosystems in New South Wales (Coutts-Smith and Downey 2006), and the cost to Australian agriculture is at least $3.5bn per year in lost production and control costs (Sinden et al. 2004).

It has taken us a long time to recognise the havoc caused to our environment by weeds, and many still fail to appreciate the scale of the problem. Too many people see the green trees or the pretty flowers and fail to understand the lost native diversity which these invaders have replaced. However, progress is being made, and all new plant imports are now subject to a Weed Risk Assessment, and can only be imported if the risk is low. Now the next step is to manage the enormous number of plants already present in Australia, in gardens and private collections, some already widespread, some naturalising in small areas and others just waiting for favourable conditions before they too become major weeds.

The first step in this process is to assemble accurate information on the plant species already here, and this database of the introduced plants of Australia does just that. Every introduced plant species present and being grown in Australia is listed, whether or not it is naturalised (ie growing in the wild), and with information on its weedy status here and worldwide.

This book is a development from Rod's database of all weedy flora of the world published in 2002 as *A Global Compendium of Weeds*. Together these two publications represent the results of years of meticulous work. *The introduced flora of Australia and its weed status* is an invaluable resource to everyone who cares about the Australian environment and wishes to ensure that the plants chosen for revegetation projects, landscaping and gardens are not likely to become weedy and a threat to our bushland.

Rachel McFadyen
CEO CRC for Australian Weed Management

Introduction

Humans are by far the most effective and efficient vector of plants around the world, and the nursery industry is a key, though not the only, commercial arm of this enthusiastic vector base. In the last 200 years a very large number of species have been introduced to Australia, including many that have not naturalised here as yet but that could potentially do so if introduced to the correct region(s) in sufficient numbers. This could easily happen if they became more popular in trade and were more widely sold and distributed, increasing propagule pressure to the point where site and circumstance meet and they become naturalised.

As a way to manage this problem, staff at an initial meeting early in the second round of the Cooperative Research Centre for Australian Weed Management proposed the development of a database of exotic plant species in Australia. A team of people interested in the idea was assembled and the project began in March 2001.

The *Exotic species database* project was originally initiated to assist in the completion of Weed Risk Assessments (WRA), the very first phase of which is to determine if the plant being assessed is already in Australia. Any plant species already present in Australia, whether naturalised here, commonly available in trade or possibly only found in the occasional plant collection, will automatically be added to the Permitted List, as long as the plant is not also a proscribed weed in any state with legal requirements to eradicate or manage.

This publication is one outcome of the project, and is aimed at a large range of users from Commonwealth, state and local government officers, to researchers, horticulturists, nursery owners, farmers, landscapers, consultants and groups of volunteers looking after remnant bushland. Everyone who uses plants needs to be aware of the weed potential of those plants and to be able to make informed decisions about which ones to use in their operations.

I hope to see a time, and not that far away, where the use of weedy plant species will no longer be accepted in public and private plantings in Australia. This publication is offered to help people to make responsible decisions in the types of plants they use in the future.

July 2007

Background

The introduction of a plant to a new region means different things to different people. With plants in particular, any definitions of introduction, incursion and invasion are full of grey areas. Different authors have offered their own definitions of the suite of terms used in invasion biology and although researchers familiar with this area are mostly in agreement the same cannot be said for others, especially those involved in plant introductions.

The word 'introduced' as used in the title itself needs explanation. In this context, the most commonly accepted definition of introduction is:

> As a result of dispersal, propagules ... arrive at a site beyond their previous geographical range and establish populations of adult plants (Richardson et al. 2000).

This definition implies that plants need to establish self-reproducing populations to be called introduced, but that is in fact the next step beyond introduction called colonisation, where the introduced plants first develop self-sustaining populations. Naturalisation is the next step where these populations start to spread beyond the point of colonisation.

For the purposes of this project, plants that have been 'introduced' do not necessarily still need to be present in Australia. They may have been introduced years ago, been grown in gardens or fields for some time, gone out of favour and disappeared from cultivation. Or they may indeed still be present in the country in cultivation somewhere but be rare or hard to find.

Many difficulties arise from the organised wholesale introduction into Australia of crop and pasture species over the last 50 to 200 years. The most successful of these were introduced very early on in the development of the Australian colonies but efforts continued over many years with thousands of accessions trialled over different areas of the country from Darwin to Hobart and Perth to Sydney.

Many of these accessions were of the same species and many were collected and referred to under old or invalid names, meaning the exact number of species introduced for trial is difficult to determine. Furthermore many accessions were not even formally identified to species level, making any attempt to produce a final list of introductions via this pathway virtually impossible.

The numbers of plants in cultivation in Australia

There are 29,430 species listed in this publication and they encompass three basic categories of taxa:

1. 26,242 introduced species under their current names, of which 25,448 of these (or 96.9%) are in cultivation. Any synonyms mentioned in this text are also listed after these names.
2. 2,582 entries of names that are synonyms of species in category one. These names are included because they are being used in media publications, catalogues and journals around Australia. The currently accepted name, as used in this text, is indicated with an equals sign (=) after these names.
3. 606 Australian native species that have naturalised outside their native ranges within Australia.

Horticultural names – Australian natives

There are a large number of horticultural or 'hort.' names, eg *Abutilon variegata* hort., that are not used in this publication. These names are not legitimate species names but are given to selections, variants or cultivars by the nursery industry. They have never been validly published and are often synonymous with a legitimately published species name. Horticultural names are only listed if the correct species name, or parents' names, could be identified. There are 259 horticultural names whose origins could not be identified and hence are not included in this publication.

Australian native species in cultivation comprise 11,119 species. As they are native, not introduced, their names are not included in this publication but their collation was essential as part of the overall project. This highlights that there is a total of 36,630 separate species in cultivation in Australia, an amazing number of plants available to horticulturists, landscape designers and plant lovers in general.

Some plants become problems

Only a small percentage of the many thousands of plant species introduced into Australia have successfully naturalised here. Of the 26,242 introduced plant species in Australia 2,739 have naturalised, leaving 23,503 species grown and cultivated now or earlier. Can these therefore be considered as valuable assets in our horticultural industries?

Unfortunately, not all of these 23,503 plant species are without risk as many are well known weeds in other countries. There are 5,907 species present in Australia which have weed histories elsewhere in the world but no current history as a weed in Australia. It is these plants that are most likely to become weeds in Australia, given the right opportunities.

The safest option is simply never to use these species in breeding programs, domestic garden plantings or landscaping projects. Restricted uses such as cultivation purely in greenhouses or air conditioned glasshouses in areas well outside their normal climate ranges could still be considered, unless the end purpose is for propagation and distribution into suitable climate regions.

Australia has a vast range of climate types and no matter how well intentioned a gardener or nursery may be those potentially weedy plants could well outlive their carers, and who is to say that the next owner will take such care or indeed even understand the risks of such species.

Even without these weedy species there is still a species pallet of just over 20,000 taxa to utilise for all horticultural purposes. This is in addition to the 11,000 cultivated Australian natives, introductions of additional new Australian natives to horticulture and new species introductions from outside Australia, screened for their weed potential by Biosecurity Australia before entry. With access to over 30,000 species of plants it is difficult to see any basis for complaints that people are being restricted in the range of plants available for use.

How to use this book

To aid people in making informed decisions about the use of a plant, its weed potential in Australia is provided as a series of shorthand codes at the end of each entry. Species are listed in alphabetical order by genus, then species with the author citation, next followed by the family the species belongs to. The codes for that species' weed status, if any data exists, are on the line after the family name.

The codes

All plants listed in this text have been introduced into Australia with the exception of the 606 natives that are known to have naturalised outside their native range within Australia. The codes used in the text are:

Weed: There is a published reference to this plant as a weed somewhere in the world.

N: This plant has naturalised somewhere in Australia.

Nn: This plant is an Australian native species that has naturalised beyond its native range within Australia.

1: This plant has been recorded as a weed of the natural environment.

2: This plant has been recorded to escape from cultivation.

3: This plant has been recorded as a weed of agriculture.

4: This plant has been recorded as a noxious (declared) weed. This is a legal category and may take the form of a prohibition on entry, sale and movement to requirements to eradicate or control.

5: This plant has been recorded as an invasive species. This is the most serious criterion that can be applied to a plant and is generally used for serious high impact environmental and / or agricultural weeds that spread rapidly and often create monocultures.

A: The capital A after any of the preceding numbers indicates that this species has met this criterion in Australia.

Obviously plants with a full range of the code numbers after their name, even if they have not yet become weed problems in Australia, are only an opportunity away from doing so. These species should never be cultivated under any circumstances. There are always other options available no matter how focused one may be on 'that' species.

Species with only one number or just the 'weed' designator could be used after investigation into where and how they are considered weedy. It may well be that many of these species will never become weeds in Australia but, just as growers would look at the agronomic implications of growing a plant, so too they should consider its weed potential.

Just because a plant is listed in this book as weedy elsewhere does not mean it will become a weed in Australia. Users need to consider where the plant is native to, its preferred climate including annual rainfall, soil type, and the ecosystems in which it is found.

Unfortunately Australia is a big country and most climate and soil types exist here. This needs to be taken into account with any plants that are to be sold widely across the country.

On the flip side our natives are tough, aggressive and able to thrive under conditions many species find too difficult. This is probably why Australian natives are rapidly naturalising all over the world and creating havoc in various ecosystems on every continent on the planet.

Used wisely and in conjunction with further research this text should assist people in avoiding potential costly mistakes that could impact on the environment. These mistakes may not become immediately evident in any one lifetime but good choices made now will rarely be as controversial, or as obvious, as the bad ones.

Note: Not all the known synonyms are included in this text, as this would have required a huge additional index and internal referencing. Therefore the synonyms included are those used in the sources from which the base dataset was composed. This nearly halves the size of the book and does not affect its useability.

A brief explanation of botanical nomenclature

For those unfamiliar with the technical standards used in naming plants, this section offers a very brief explanation of the methodologies used to name plants. The botanical or scientific name is the accepted standard name for a plant. Each plant has a unique botanical name that is described and named by its author in Latin. This is the most accurate way of referring to a plant as many plants have similar or the same common names and regional variations and differences can cause no end of confusion. Latin is used because it is a dead language and therefore not prone to change.

Family – The family is the botanical category above genus. Each family contains many genera (the plural of genus) that share characteristics. For example *Rosa canina* is in the family Rosaceae whose members share a number of features. There are several more groupings of plant types above family leading ultimately to the Plant Kingdom.

The botanical name of a particular plant is made up of two parts; the first is the genus, the second is the species epithet. The botanical name is always written in *italics* with the genus name capitalised and the species and any other names all in lower case. For instance, the plant commonly referred to by many as the 'dog rose' is known by the botanical name, *Rosa canina* L. In this example, the species epithet is *canina*. So, while there are many plants in the genus *Rosa*, there is only one known as *Rosa canina*. Taken together, *Rosa canina* L. is referred to as a species.

Genus – The genus is the lowest level of plant relatives before individual species are described. A genus can contain from one to many hundreds of species names. A genus with only one species is called monotypic (one type).

Species (spp.) – The species name is not the end of the taxonomic trail, however, with several lower levels of taxonomic distinction being applied by taxonomists. A highly variable species may have many subspecies, varieties, subvarieties, forma etc named by taxonomists. For our purposes identification to species level is sufficient but it pays to understand that subspecific levels of nomenclature do exist. A brief explanation of the most commonly used subspecific nomenclature follows.

Subspecies (subsp. or ssp.) and Varieties (var.) – These are taxonomic groups that are a distinctive subdivision of a species whose members have certain hereditary characteristics distinct from other populations of that species.

Cultivar (cv.) – A cultivar is a plant created by careful selective breeding often using inter or infra generic hybridisation (within or between related genera). Most cultivars are registered by their breeders and given names. Often people will quote a cultivar name in the mistaken belief it is a species name. As one species name can contain many dozens if not hundreds of cultivars it pays to appreciate the difference. Cultivars are not considered part of the 'natural' chain of botanic taxonomy due to their artificial origin but are acknowledged after the author name in most descriptions when mentioned in publications (example below).

Examples of correctly cited cultivar and hybrid names:

Cultivar examples

- *Acer negundo* L. 'Flamingo'
- *Malus baccata* (L.) Borkh. 'Lady Northcliffe'

Hybrid examples

- *Alocasia* X *amazonica* André (a hybrid of *Alocasia lowii* Hook. f. and *Alocasia sanderiana* W.Bull)
- *Primula* X *bulleesiana* Janson (a hybrid of *Primula bulleyana* Forrest and *Primula beesiana* Forrest)

Synonyms – Sometimes a plant that has received a botanical name from one author is given a new name by another author. These old names become synonyms of the currently accepted names and while no longer in use still exist in old publications, and often in popular use in trade. It's important to keep track of these names to maintain the connections between the old and the new names, eg *Vesalea floribunda* M.Martens & Galeotti is a synonym of *Abelia floribunda* (M.Martens & Galeotti) Decne.

The author

The person who identifies a plant with its unique botanical name by publishing its description in a botanical or taxonomic journal becomes its author. *Rosa canina* was named by Carolus Linnaeus in 1753. Linnaeus developed the binomial (two name) system of plant taxonomy we use today and he himself named a great many plants. An author's name is usually written in full or a slightly abbreviated form after the binomial name but Linnaeus is abbreviated simply to 'L.' being rightly considered the father of botanical nomenclature.

There is also the issue of name changes. Taxonomists often reallocate species into other genera, or split a single species into multiples. This can be followed to some extent by the author citation that appears after the species name as the following example shows.

Vesalea floribunda was originally named by Martin Martens and Henri Guillaume Galeotti in 1844 and was then correctly cited as *Vesalea floribunda* M.Martens & Galeotti. Two years later Joseph Decaisne decided to place this species into the genus *Abelia* and renamed it *Abelia floribunda*. While it is acceptable to replace the old authors with the latest author when citing a plant name it is useful to provide any previous authors, bracketed and in front of the current author, ie *Abelia floribunda* (M.Martens & Galeotti) Decne. This alerts people to any past name changes, synonyms etc that could provide more information on the species in question.

A quick guide to understanding this publication

In the binomial system for naming plants this first name is called the genus. Latin is normally used for these names and they are always italicised and the genus always capitalised.

The second name is the species name and the combination of the genus and species names provides a unique identifier for every published plant. The species name is always in lower case.

Every published plant name has an author, or authors, associated with it. Often a plant name is allocated to the wrong genus or a species is split into several more.

If a species name is changed, the original authors can be bracketed and placed before the latest author. This can be useful as it alerts one to the possibility of synonyms.

This is the plant family to which the genus *Abelia* belongs.

The family is the botanical category above genus.

Abelia floribunda (M.Martens & Galeotti) Decne.
Linnaeaceae

Abelmoschus moschatus Medik.
Malvaceae
◆ Weed - **Nn** - 1 - 2 - 5

◆ Weed

Potentilla cuneata Wall.
Rosaceae
◆ Weed - 2

Potentilla delphinensis Gren. & Godr.
Rosaceae

Potentilla dombeyi Nestl.
Rosaceae

Potentilla drummondii Lehm.
Rosaceae
See: *Potentilla breweri* S.Wats.

Potentilla erecta (L.) Raeusch.
Rosaceae
See: *Potentilla tormentilla* (Stokes) Neck.
◆ Weed - 1 - 2

Potentilla eriocarpa Wall. ex Lehm.
Rosaceae

Potentilla fissa Nutt.
Rosaceae

Potentilla fragiformis Willd. ex Schlecht.
Rosaceae
◆ Weed

Potentilla frigida Villars
Rosaceae

Potentilla fruticosa L.
Rosaceae
= *Dasiphora fruticosa* (L.) Rydb.
◆ Weed - 2

Potentilla fulgens Wall. ex Lehm.
Rosaceae

Potentilla geoides Bieb.
Rosaceae

Potentilla glandulosa Lindl.
Rosaceae
◆ Weed

Potentilla gracilis Douglas ex Hook.
Rosaceae
◆ Weed - 3

Potentilla grandiflora L.
Rosaceae

Potentilla haynaldiana Janka
Rosaceae

Potentilla heptaphylla L.
Rosaceae

Potentilla hippiana Lehm.
Rosaceae

Potentilla hookeriana Lehm.
Rosaceae

Potentilla indica (Andrews) Th.Wolf
Rosaceae
◆ Weed - **N**

Potentilla intermedia L.
Rosaceae
◆ Weed - 3 - 5

Potentilla megalantha Takeda
Rosaceae

Potentilla montegrina Pant.
Rosaceae

Potentilla nepalensis Hook.
Rosaceae
◆ Weed - 1 - 2

Potentilla neumanniana Rchb.
Rosaceae
See: *Potentilla crantzii* (Crantz) Beck ex Fritsch, *Potentilla tabernaemontani* Asch., *Potentilla verna* auct. non. L.

Potentilla nipponica Th.Wolf
Rosaceae

Potentilla nivea L.
Rosaceae

Potentilla palustris (L.) Scop.
Rosaceae
= *Comarum palustre* L.
◆ Weed - 2

Potentilla pensylvanica L.
Rosaceae
◆ Weed

Potentilla pulcherrima Lehm.
Rosaceae

Potentilla recta L.
Rosaceae
◆ Weed - **N** - 1A - 2 - 3 - 4 - 5

Potentilla reptans L.
Rosaceae
◆ Weed - **N** - 1A - 3 - 5

Potentilla rupestris L.
Rosaceae
◆ Weed - 3

Potentilla supina L.
Rosaceae
◆ Weed - **N** - 3 - 5

Potentilla tabernaemontani Asch.
Rosaceae
= *Potentilla neumanniana* Reichenb.
◆ Weed

Potentilla thurberi Gray
Rosaceae

Potentilla X *tonguei* Baxter
Rosaceae

Potentilla tormentilla (Stokes) Neck.
